Domain Registration And Web Hosting

In today's world of technological advancement and super fast connectivity, a website is the best means of promoting ones business. It is almost a necessity today, even for basic functions of modern life, such as paying bills, booking trips, buying books, searching for homes, or reading the news. Therefore, one has to own a website but creating a website and getting it online can be a tricky job, especially for the common public. And this surely isn't helped by the common confusion that domain registration and web hosting is one and the same thing. Most online services these days offer both of these services, so it is really necessary to understand the differences.

Domain registration and web hosting are two separate processes which need to be completed before creating a website. Firstly, a domain must be registered by a domain registration company and then that domain name must be hosted on the internet through a web hosting company. The first step in the process of setting up a domain is domain registration. If you wish to create your own website, you need to name your website. To ensure that it is unique and that you become the legal owner of that domain name, you need to register it with a domain registration company.

You also need to pick a domain extension such as .com, .co, .uk, .org, .net etc. You should give careful consideration to the domain extension you choose to ensure that your full domain name best represents that of your business or project. To be sure of the credibility of the domain registration company always get it done through ICANN-accredited registrars, who collectively maintain the shared registration system (SRS).

Once you have completed the process of domain registration, you need to get your website live on the internet. To do this, you need to buy a web hosting package from a hosting company. The type of web server your site is hosted on will depend on the requirements of your website. Normally, this choice would depend on the scripting language used for the website. If the scripting languages used in your website are PHP, MySQL or Perl. Then you need to go in for Linux Web Hosting. Linux web hosting includes features such as a certain space storage, data transfer capacity, email and script installer facility, real time statistics, sub domains, anti-virus, dedicated IP addresses, private DNS servers, web host manager panel, control panel with power features, DR11 memory, transfer capacity and full system administration. Linux web hosting enhances the operational structure of websites and provides them with the requisite support for running websites and applications successfully.

These were some of the differences between domain registration and web hosting. Now armed with all this information you can easily create a website of you own. For registration and hosting plans log on to www.Bigrock.com
